Abstract

Previous work has demonstrated that cued recall of a term from a fact yields learning that does not transfer, relative to a restudy control, to recall of another term from the same fact. Here we report six experiments in which a series of manipulations during the initial study and training phases of learning, intended to increase transfer for process-based biology concepts, were investigated. In Experiments 1-2, fill-in-the-blank questions combined with immediate or delayed and repeated correct answer feedback improved learning but not transfer. In Experiments 3-4, practice questions which involved recalling process steps, understanding ordinal relationships, or making inferences, did not improve transfer. Positive transfer was produced, however, in Experiments 5-6 via *retrieval-verification-scoring*, a method in which difficult fill-in-the-blank questions were combined with extensive feedback processing. We discuss implications for transfer in both theoretical and applied contexts.

Keywords: cued recall; transfer; testing effect; retrieval practice; feedback

In Search of Transfer Following Cued Recall Practice:

The Case of Biology Concepts

Across virtually all areas of STEM education, the learning and retention of process-based concepts is an essential step for achieving mastery. For current purposes, a process-based concept is defined as a sequence of events that occur over time, leading to a predictable end state. Such concepts are ubiquitous in the target domain of this manuscript, namely introductory biology. A classic example is the concept of *protein synthesis*. It involves the following process: *DNA is first copied into RNA via transcription, and then RNA is coded into protein via translation* (Freeman, Quillin, & Allison, 2014). In that concept, two sequential processes, transcription and translation, result in the formation of protein.

Given the ubiquity and foundational nature of such materials, it is important to understand how students can learn them efficiently (i.e., with the least time invested), durably (i.e., yielding long-term retention), and comprehensively. One promising approach is *retrieval practice with feedback*. Retrieving information from memory, as occurs on a practice test, yields robust learning benefits over restudy and other non-retrieval methods. That finding, commonly known as the *retrieval practice effect* or *testing effect*, has been observed across a wide range of educationally-relevant materials (e.g., Dunlosky, Rawson, Marsh, Nathan, & Willingham, 2013), using different test formats (e.g., Kang, McDermott, & Roediger, 2007), with diverse learners (e.g., Pan, Pashler, Potter, & Rickard, 2015), and under different levels of motivation (e.g., Kang & Pashler, 2014). The effect is enhanced if *correct answer feedback* is provided after attempting retrieval, and it persists over time; the relative advantage of retrieval practice over restudy increases with longer retention intervals (e.g., Carpenter, Pashler, & Cepeda, 2009; Rowland, 2014). Given these findings, retrieval practice would appear to be well-suited to enhance the learning and transfer of process-based concepts – a possibility that we explore in this manuscript.

Specificity of Learning Through Cued Recall Practice

In the research literature (see Rickard & Pan, 2017), and quite likely also in current educational practice, the most commonly used variant of retrieval practice is *cued recall*, in which part of a studied item is presented on the initial test as a cue, and the remainder of the item is to be retrieved from memory. For the concept given above, an example cued recall question (in fill-in-the-blank format) is: “*In protein synthesis, DNA is first copied into RNA via _____?*” There is overwhelming evidence that cued recall facilitates, relative to restudy, subsequent retrieval of the same term that was retrieved on the initial test (i.e., the test that occurred during training). However, there is equally strong evidence that for educationally-relevant materials (e.g., fact learning), that facilitated learning does not extend, or *transfer*, to questions from the same stimulus that require a different term response. For example, in Pan, Gopal, and Rickard (2015), cued recall involving the fill-in-the-blank question, “*Thomas Jefferson purchased _____ from Spain,*” for which the answer is *Louisiana*, yielded substantial learning relative to restudy when that same question was again asked after a delay, but did not yield transfer to “*Thomas Jefferson purchased Louisiana from WHOM?*” relative to restudy. Rather, criterial test performance on such items was equivalent to performance after restudy. Similar findings have been reported by Hinze and Wiley (2011) and Pan and Rickard (2017); one exception is McDaniel, Anderson, Derbish, and Morrisette (2007), which is discussed later in this manuscript. Thus, although retrieval practice appears to be at least as effective as restudy in all instances, it is, in work to date, evidently superior to restudy only for the initially tested term (for a review, see Pan & Rickard, 2018).

It however remains to be determined whether the extreme specificity of learning through cued recall testing is universal for facts and concepts, or whether there are conditions, heretofore unexplored, in which positive transfer will be observed. For instance, in many retrieval practice

studies, target materials are studied relatively briefly and without supporting information (e.g., explanatory diagrams); it has yet to be established whether the same patterns would manifest for more enriched and more extensively studied information. Further, researchers have hypothesized that some forms of retrieval practice, including the use of questions that invoke processing of conceptual relationships, yields more transferrable learning (e.g., Jensen, McDaniel, Woodward, & Kummer, 2014). There has also been some research and theorizing which suggests that feedback that is processed for greater lengths of time and/or contains more than just the correct answer can enhance transfer (e.g., Butler, Godbole, & Marsh, 2013; see also Eglinton & Kang, 2017; McDaniel & Little, in press). If feedback is the critical factor, then that would potentially constitute an *indirect* transfer effect (i.e., transfer that does not stem wholly from the retrieval event itself; for discussion see Roediger & Karpicke, 2006; Pan & Rickard, 2018). Learning benefits that stem solely from performing retrieval (e.g., as can occur for correctly answered cued recall without feedback) constitute *direct effects* of retrieval practice, whereas learning benefits stemming from activities besides the retrieval event, such as post-retrieval processing of feedback, constitute indirect effects.

Additionally, in the studies of cued recall and transfer noted above, the target materials were typically not process-based. For instance, none of the facts in Pan, Gopal, et al. (2015), which included materials drawn from AP History and Biology courses, described a sequence of processes. Rather, for history they focused on details of the “who, what, when, and where” variety, and for biology they typically took the form of *x of y and z* (e.g., “*The exoskeletons of most insects are made of chitin.*”). By contrast, the current experiments explicitly involved only process-based biology concepts. Thorough learning of such concepts might yield a richer, or deeper level of knowledge representation than does learning of non-process-based concepts or facts, which in turn might support positive transfer of cued recall relative to restudy.

Overall, across the six experiments detailed here, we explored three distinct types of cued recall with multiple forms of feedback that might promote transfer (see Table 1 for a summary of training methods). Although this series of experiments is systematic and is largely motivated by prior empirical or theoretical work, it is also exploratory, especially in the latter experiments.

Overview of the Present Experiments

In each experiment, subjects first studied 24 or 36 process-based concepts one at a time in random order. The concepts were drawn from a widely-used undergraduate biology textbook (Freeman et al., 2014; see Appendix A for a list). To enhance conceptual understanding and to promote more comprehensive learning, each concept was presented with a visual-conceptual diagram and a glossary of term definitions (see Figure 1 for an example). Subjects were instructed to study each concept carefully and to do so at their own pace. The decision to provide diagrams and definitions was motivated by a preliminary experiment in which those materials were not provided during initial study and in which no transfer was observed.

Training methods. After the initial study period, subjects completed a training phase in which each concept was trained with cued recall or restudy. Across six experiments, three retrieval practice methods were used (see Appendix B for examples): *term retrieval* (Experiments 1-2; fill-in-the-blank questions in which a missing term was to be retrieved), *higher order questions* (Experiments 3-4; primarily short answer questions in which a process step needed to be retrieved, the relationship between terms needed to be identified, or inferences about the concept had to be made), and *retrieval-verification-scoring* (Experiments 5-6; a new method in which the entire concept, excepting one or two cue terms, had to be retrieved, followed by a series of feedback processing methods).

Feedback methods. We implemented feedback in six different ways. This included three feedback types (see Appendix B for examples): *simple correct answer feedback*

(Experiment 1) which involved just the term that was supposed to be retrieved (e.g., *transcription*); *process timelines* (Experiment 2) which involved a timeline of the underlying conceptual process (e.g., *DNA — transcription — RNA — translation — protein*); and *whole concept feedback* (all except Experiment 1) which involved presentation of the entire concept in text form.¹ Feedback was presented and processed using three different methods: *immediate feedback* (all except Experiment 2); *delayed and repeated feedback* (Experiment 2); and feedback in which subjects checked terms, scored their performance on those terms, and then copied the entire presented concept (i.e., *retrieval-verification-scoring*; Experiments 5-6). Those which involved more than immediate correct answer feedback can be classified as *elaborative* forms of feedback (Butler, Godbole, & Marsh, 2013). Any of these methods might enhance indirect effects of retrieval practice.

Criterion test. Two days after training, subjects completed a self-paced short answer criterion test. This criterion test, modelled after that used in Pan, Gopal, et al. (2015) and Pan, Wong, Potter, Mejia, and Rickard (2016), was identical across all experiments and featured three contiguous blocks in which each concept was tested once per block and with a different to-be-retrieved term per block (e.g., for *protein synthesis*, *transcription*, *translation*, and *RNA* were assessed). The instructions directed subjects to recall the exact terms that they had previously learned for each concept. No feedback was provided.

Based on prior literature, it was expected that there would be a substantial benefit of cued recall on the criterion test for terms that were previously tested (*tested-same* condition), relative to terms from concepts that were restudied (*restudied* condition). The primary question of interest was whether there would be a benefit of cued recall for previously untested terms from tested concepts (*tested-different* condition) versus the restudied condition, and under what training conditions such a benefit would manifest.

Experiment 1

The first experiment served to assess whether the cued recall and feedback methods used in prior studies of cued recall and transfer across terms from facts could yield transfer for process-based biology concepts that were supplemented by diagrams and definitions during initial study. It was the first of two experiments in which *term retrieval* questions were used during training. *Simple correct answer feedback* was also implemented in this experiment only.

Method

Subjects. In all experiments, subjects were recruited from the same subject pool and identically compensated. In Experiment 1, fifty-eight undergraduate students recruited from a large research university participated for course credit. Data from one subject was excluded due to computer error, leaving 57 subjects' data for analysis. That sample size well exceeded our per-experiment target (a sample size of 45 is needed to achieve 0.85 power to detect a mean proportion correct difference between the tested-same or tested-different condition and the restudied condition of 0.04 or greater on a one-tailed, one-sample *t*-test at $\alpha = .05$, based on the a priori power analysis reported in Pan, Gopal, et al., 2015).

Design and procedure. In this and all subsequent experiments, the independent variable, namely training via cued recall testing versus restudy, was manipulated within-subjects. There were two experimental sessions. In the first session, subjects were first informed that their task was to learn a series of biology concepts. An initial study period followed in which 36 concepts were studied one at a time as previously described. This was followed by a training phase in which each concept was tested or restudied once for 10 s each. Testing and restudy trials were randomly ordered within a single contiguous training block. Testing involved a single fill-in-the-blank test question with immediate correct answer feedback (presented for 8 and 2 s, respectively) and restudy involved viewing the concept in sentence form. After a two-

day delay, subjects returned for the criterial test as previously described.

Materials. The materials consisted of 36 process-based biology concepts drawn from Freeman et al. (2014). Each concept was a biological process involving at least two discrete steps and took the form of a single sentence with a mean length of 18 words. The mean Flesch-Kincaid reading grade level of the concepts was 12.8. Three essential terms that represented crucial components or steps were identified for each concept (e.g., *transcription*, *translation*, and *RNA*). There was largely minimal overlap in content and no terms shared between concepts. Three fill-in-the-blank training questions and three corresponding short answer criterial test questions, each targeting one of those terms, were created for each concept. The criterial test questions were identical to the training questions except for the use of the word “*WHAT*” in place of the answer blank.

Visual-conceptual diagrams and term definitions. During initial study, each concept was presented in sentence form and accompanied by a visual-conceptual diagram and a glossary of term definitions (see Figure 1). Both appeared only during that portion of the experiment and were intended to aid subjects’ understanding of the concepts, many of which included unfamiliar jargon (e.g., terms such as *cochlea*, *effector*, *phospholipid*). The diagram consisted of a colour drawing of conceptual processes with arrows specifying individual steps or movements. Labelled representations of each of the three essential terms, plus any other jargon terms or important steps, were included with each diagram. The glossary defined each of the three essential terms for each concept plus any other jargon terms that were also present. Each term on the diagram and in the glossary was present in exact matching form in the concept sentence.

Training and criterial test lists. Each subject trained using one of six counterbalanced training lists. There was one training trial per concept on each list. Half of the concepts were tested using a fill-in-the-blank question and the remainder was restudied. Assignment of concept

to cued recall testing or restudy, and the question that was used for each concept (i.e., the term needed to be retrieved), was counterbalanced using a Latin square. Six additional test lists, each corresponding to one of the training lists, were used for the criterial test. Each criterial test list contained three blocks of 36 short answer questions each, with each concept assessed once per block and on one of the three terms per block. There were 6 tested-same questions, 12 tested-different questions, and 18 restudied questions per block on the criterial test.

Data coding and analysis. Training and criterial test data were computer scored. Typed responses that exactly matched the correct answer (ignoring capitalisation) were scored as correct. In this and all subsequent experiments, we performed two planned orthogonal contrasts that were motivated by prior findings of no transfer: (a) an Analysis of Variance (ANOVA) with factors of Tested-same vs. Not Tested (i.e., the tested-same condition vs. the tested-different and restudied conditions combined) and Block; and (b) an ANOVA limited to data from the tested-different and restudied conditions only, with factors of Tested-different vs. Restudied, and Block. This latter contrast directly tested for transfer relative to restudy. We used a significance criterion of $\alpha = 0.05$ for all statistical analyses.

Results

Initial study and training. Subjects spent an average of 19 min studying the concepts, or about 31 s per concept. During training, they typically retrieved the correct answer to less than one-third of the questions ($M = 0.27$) prior to viewing feedback (Table 2). This relatively low rate of retrieval success (as compared to typical rates in the literature; catalogued in Pan & Rickard, 2018) underscores the difficulty of learning process-based biology concepts despite the presence of diagrams and definitions during initial study.

Criterial test. Results are listed in Table 3 and depicted in Figure 2, panel a. An important initial observation is that criterial test performance across all blocks in the tested-same

condition was substantially higher than that during training ($M = 0.50$ vs. $M = 0.27$), confirming the expectation that training yielded substantial learning in that condition. In the first ANOVA contrast with factors as previously described (Table 4), there was a main effect of Tested-same vs Not Tested. This is consistent with a retrieval practice effect for previously tested items as is evident in Figure 2. There was also a main effect of Block and no interaction. This is consistent with a performance improvement across blocks, an expected pattern given that the answers to criterial test questions in blocks 2 and 3 were viewable in preceding blocks. In the second contrast, there was no main effect of Tested-different vs. Restudied, which is consistent with there being no benefit of cued recall for untested terms relative to restudy. In other words, there was no evidence of positive transfer.

Effect of prior course experience. In this and subsequent experiments, exit surveys revealed that 53-77% of subjects had university-level biology or AP Biology course experience. Those with experience tended to perform better overall, but transfer patterns did not differ substantially between groups (similar to Pan, Gopal, et al., 2015; Pan & Rickard, 2017). Thus, we do not further discuss results as a function of course experience.

Discussion

In this experiment, although there was a benefit of cued recall for tested terms, there was no evidence of transfer of that learning to the tested-different condition. This result replicates the findings of Pan, Gopal, et al. (2015) using non-process-based materials supplemented by diagrams and definitions and with similar training methods. Further, in two unpublished follow-up experiments not detailed here, we observed the same results when a different term had to be retrieved on each of two training blocks, similar to Pan, Wong, et al. (2016; Experiment 2), and when two terms had to be retrieved per trial, similar to Hinze and Wiley (2011; Experiments 1 and 2) but with feedback. Thus, the benefits of cued recall combined with simple correct answer

feedback appears to be specific to tested terms for the case of process-based concepts in the context of diagram- and definition-augmented study, extending our prior results.

Experiment 2

In the literature there has been one successful demonstration of transfer from tested to untested biology terms, relative to restudy, using fill-in-the-blank cued recall tests. McDaniel, Anderson, et al. (2007) had students enrolled in a university-level brain and behavior course initially learn target materials via assigned readings and classroom lessons. The students then completed practice quiz questions online over three weeks and in preparation for a later unit test. Question-by-question feedback consisting of the attempted answer and the correct answer was provided only after each quiz was submitted. That feedback could be viewed repeatedly until the date of the unit test, on which positive transfer was observed relative to restudy (albeit without strict controls for time-on-task during training in the testing and restudy conditions). None of those design features were present in our initial experiment. Thus, to bridge the differences between Experiment 1 and that prior work, and to further improve the level of learning that subjects achieved for each concept with the aim of observing transfer, in Experiment 2 we implemented multiple exposures to each concept during a standalone initial study session (designed to approximate lessons and readings that students may complete before using retrieval practice), had subjects train on those concepts with *delayed and repeated feedback*, and included *whole concept feedback* in which *process timelines* were shown. This design was intended to conceptually replicate McDaniel, Anderson, et al.'s experiment in a laboratory setting.²

Method

Subjects. Forty-seven subjects participated for course credit. Data from 4 students were excluded, 2 due to a computer error and 2 due to not following instructions, leaving 43 subjects that were included in the data analysis.

Design and procedure. Uniquely in this experiment, there were three experimental sessions. The first session was entirely devoted to initial study of the concepts. Subjects began that session by cycling through each concept repeatedly for 30 minutes. During that period the concepts and term definitions were presented in paragraph form (see Appendix C for an example) with supporting diagrams. Next, subjects cycled through each concept repeatedly for an additional 30 minutes. During this time each concept was presented only in sentence form.

Training methods. The second session occurred 48 hrs after the first. During this session, subjects trained on the concepts using fill-in-the-blank tests or restudy across separate blocks, presented in random order. Each training block lasted 12 min. During the test block, subjects answered one fill-in-the-blank question per tested concept. After all questions were answered, they viewed question-by-question feedback. That feedback consisted of the whole concept in sentence form, their attempted answer, and a process timeline. They were instructed to cycle through that feedback repeatedly at their own pace until time had elapsed.

The restudy block had a similar structure. Subjects first viewed each restudied concept once in sentence form. They next viewed those concepts again in sentence form and with process timelines, similar to the test condition. They were instructed to cycle through those concepts repeatedly at their own pace until time had elapsed. The second session ended after both training blocks were finished. Finally, after a second 48 hr delay, subjects returned for a criterial test that used the same design as that of the prior experiment.

Learning instructions. Uniquely in this experiment, the instructions at the outset of session two informed subjects that they would be training for an exam in session three. Moreover, at the outset of the test block, they were told that the practice questions resembled exam questions, but that any part of a tested concept could be assessed on the exam; thus, they should learn entire concepts. During the restudy block, subjects were told to study.

Materials. The materials consisted of 24 biology concepts drawn from the set used in the preceding experiment, a reduction due to the logistics of experiment scheduling, and with training and criterial lists altered to match. For initial study, a textbook paragraph-style version of each concept, using short sentences and with term definitions embedded within the paragraph, was created. The paragraphs had a mean length of 79 words and a Flesch-Kincaid reading grade level of 11.3. For feedback, a timeline of process steps was created for each concept as previously described. All other materials were identical to those in the prior experiment.

Results and Discussion

Initial study and training. During the first and second halves of the initial study period, respectively, subjects viewed each concept an average of 6 and 4 times (for 21 and 31 s each). During training, subjects cycled through delayed feedback an average of 8 times per tested concept (11 s per concept) and 7 times each per restudied concept (16 s per concept). Subjects' training accuracy was $M = 0.62$, a substantial improvement over Experiment 1 (Table 2). This is especially notable given that training took place 48 hrs after initial study, which allowed more time for forgetting to have taken place, and suggests that the standalone initial study session enabled subjects to attain a higher level of understanding of each concept.

Criterial test. Results are listed in Table 3 and depicted in Figure 2, panel b; ANOVA results are listed in Table 4. As is evident in the figure, criterial test performance was improved over the preceding experiment across all conditions. Moreover, for the tested-same condition, performance is near ceiling. These results likely reflect the more extensive initial study and training methods that were used. However, the now-familiar pattern, namely a retrieval practice effect for tested-same terms and minimal transfer to tested-different terms relative to the restudied condition, was still observed. Thus, in this experiment we were unable to reproduce the findings of McDaniel, Anderson et al. (2007) in a laboratory setting and despite using many

of the same training methods (albeit without learning in the context of an actual class, or training on multiple sessions across several weeks – issues that we further address in the General Discussion). Overall, the results of both Experiments 1 and 2 reinforce our conclusion that cued recall in the form of simple fill-in-the blank questions tends to yield highly specific learning. Moreover, the results of Experiment 2 rule out the hypothesis that delayed and repeated feedback that includes more than just correct answers (i.e., to fill-in-the-blank questions) is always sufficient to yield indirect transfer to untested terms.

Experiment 3

The third experiment was the first of two experiments in which we investigated retrieval practice methods that require learners to consider connections between different components of a concept. In the literature, some researchers have suggested that *higher order* questions, including questions that require subjects to retrieve more than just an isolated portion of a fact or concept, yields better overall understanding and may improve certain types of transfer (e.g., Jensen et al., 2014; Karpicke & Aue, 2015). Accordingly, in this experiment each tested concept was trained four times using two question types: *process step* questions, which required retrieval of half of each concept from memory, and *order* questions, which required the determination of the ordinal relationship of two terms from a concept. The use of two question types also introduced variation (i.e., potential encoding variability) in the types of retrieval practice performed for each tested concept.

Method

Subjects. Fifty-four subjects participated for course credit. Data from 4 subjects was excluded due to computer errors and 7 subjects did not return for the second session, leaving 43 subjects' data for analysis.

Design and procedure. The primary difference in this experiment was the training

phase design. Subjects completed four successive training blocks in which each concept was tested or restudied once per block for 20 s (and for test trials, 10 s for retrieval and 10 s for feedback). Test and restudy trials were randomly intermixed in each block. With this experiment we also reverted to having both initial study and training occur in an initial session.

Training methods. For process step questions, subjects were given the name of the concept and asked, “*What occurs in the first step? Answer completely with all details.*” (or that question but with *second* instead of *first*). For order questions, subjects were presented with the name of the concept, two terms in alphabetical order, and asked, “*Which of these occurs first in the process?*” (or that question but with *second* instead of *first*). Thus, order questions constituted a form of two-alternative forced choice question, marking the sole deviation from cued recall in the present experiments. Importantly, each tested concept was trained with one process step question and one order question, with each concept tested once per block and on one question type per block. Whole concept feedback was provided immediately after each retrieval attempt. On restudy trials, subjects viewed entire concepts in sentence form.

Learning instructions. To answer test questions, subjects were told to think of the entire concept, including its constituent processes; to recall exact words; and to check feedback word-by-word for complete comprehension. For restudy trials, subjects were told to study.

Materials. To facilitate process step questions, all 36 concepts were reworded into two separate sentences that identified the two main steps for each concept in sequence using the connective words “*first*” and “*second*” or “*as a result*” (e.g., *protein synthesis involves two steps. In the first, DNA is first copied into RNA via transcription. In the second, RNA is coded into protein via translation.*). The sentences had a combined mean length of 17 words and a Flesch-Kincaid reading grade level of 7.6, the reduction in grade level due to the added connective words. Each concept was presented in two-sentence form throughout the experiment.

Two process step and two order questions were created for each concept, one per step, with the assignment of question to concept counterbalanced across six training lists. The names and terms of several concepts were modified to avoid overlapping between cues and responses. Each order question required subjects to select between two terms, one from each step. For each subject, the correct answer to the process step and order questions for each tested concept referred to the same step (e.g., if retrieval of the first step was required for the former question, then identifying a term from the first step was required for the latter question). On the criterial test, which was identical at the trial level to that of the prior experiments, two terms from that step were assessed in the tested-same condition and one term from the other step (i.e., the lure in the order question) was assessed in the tested-different condition (cf. Little, Bjork, Bjork, & Angello, 2012). There were 12 tested-same questions, 6 tested-different questions, and 18 restudied questions per criterial test block.

Data coding. All process step questions were scored by raters blind to condition using a rubric of idea units for each concept (following the method detailed in Pan & Rickard, 2017). All other questions were computer scored in the same manner as in the preceding experiments.

Results and Discussion

Initial study and training. Subjects spent an average of 23 min, or 38 s per concept, during initial study. During training (Table 2), mean performance improved from the first to second administrations of each process step and order question (reaching $M = 0.54$ and 0.87 , respectively).

Criterial test. Results are listed in Table 3 and depicted in Figure 2, panel c; ANOVA results are detailed in Table 4. The same overall pattern as in the prior experiments was again observed. Mean performance in the tested-different condition reached parity with the tested-same condition by block 3, but the interaction with Block was not significant. Moreover, across

blocks 1 and 2, there was little indication of positive transfer, and the first block constitutes the purest measure of learning from the first session. Thus, although process step and order questions required a greater understanding of the relationship between different components of each tested concept than term retrieval questions, and also targeted each concept in different ways (albeit with some overlap in content), using those questions in conjunction with whole concept feedback still yielded specific learning as in the earlier experiments.

Experiment 4

In the fourth experiment, we continued our investigation of higher order questions by having subjects train on concepts using process step questions and *inference questions*. This latter question type required subjects to integrate information about each tested concept in a different way from that in which it was originally presented, which might promote greater conceptual understanding and improve transfer (Jensen et al., 2014).

Method

Subjects. Forty-nine subjects participated for course credit. Data from 5 subjects was excluded due to computer or experimenter error and 1 subject did not return for the second session, leaving 43 subjects' data for analysis.

Design and procedure. The design and procedure were identical to that of the preceding experiment, except that inference questions were used in place of order questions. Directions to think of entire concepts, recall exact words, and completely check feedback were provided for test trials, just as in Experiment 3.

Materials. One of the authors with experience as a biology section instructor created an inference question for each of the 36 concepts. These questions replaced the order questions on the training lists. Depending on the concept, the inference question required integrating multiple pieces of information (e.g., “*what is the purpose of plasmogamy in fungal cells?*”), identifying a

critically important component or process (e.g., “*the process of gene flow affects what aspect of a population?*”), or determining a hypothetical state of a conceptual process (e.g., “*if protein synthesis could be reversed, what molecule would you end up with?*”). The answers to these questions did not necessarily refer to any of the essential terms for the tested concept but could be derived from the provided whole concept feedback.

Data coding. All process step questions were scored using same procedures as in the prior experiment, with those procedures adapted for scoring inference questions.

Results and Discussion

Initial study and training. Subjects spent an average of 23 min, or 37 s per concept, during initial study. During training (Table 2), mean performance improved from the first to second administrations of each process step and inference question (reaching $M = 0.57$ and 0.70 , respectively).

Criterial test. Results are listed in Table 3 and depicted in Figure 2, panel d; ANOVA results are detailed in Table 4. The same overall pattern as in the prior experiments was yet again observed. Moreover, mean performance in the tested-different condition was lower than the tested-same and restudied conditions in block 3. That apparent negative transfer was evident in the orthogonal contrasts (Table 4), but is an anomalous result in the context of all prior results and may thus reflect random variance. Overall, the results of Experiments 3 and 4 are inconsistent with the hypothesis that higher order questions of various types always yield transferrable learning, at least for the case of transfer to untested terms.

Experiment 5

Given the prior failures to observe positive transfer, we next investigated more extensive cued recall and feedback techniques. We hypothesized that subjects (a) had to be made aware of the importance of including multiple exact terms in their retrieval attempts through actual

experience and not just through instructions; (b) their attention had to be specifically directed to each essential term in each tested concept; and (c) they had to focus on both while processing feedback. To achieve these goals, we drew inspiration from Rawson and Dunlosky's (2011) use of *retrieval-monitoring-feedback* trials in which subjects had to check each of several main ideas per retrieved definition; without such checking, subjects could erroneously regard incomplete answer attempts as fully correct. We ultimately developed a new training technique, *retrieval-verification-scoring*, which involved recalling nearly entire concepts and then checking terms, scoring terms, and viewing and copying whole concepts. This was a far more time-consuming procedure than in prior experiments, potentially boosting transfer at the cost of efficiency and complexity. Moreover, given the extensive use of feedback on each test trial, any observed transfer could be attributed to indirect effects of retrieval practice.

Uniquely in this experiment, rather than setting a total time limit across the test and restudy conditions (which given the more time-consuming nature of retrieval-verification-scoring trials under self-paced training would have yielded large disparities in the number of trial repetitions per concept), we equated the total trial repetitions per concept across training conditions (i.e., three repetitions each). Further, to equate the amount of word-for-word copying that occurred in both conditions, we implemented copying during both test and restudy trials.

Method

Subjects. Fifty-seven subjects participated. Data from 6 subjects was excluded due to computer or experimenter errors and 5 subjects did not complete the second session, leaving 46 subjects' data for analysis.

Design and procedure. Only the training phase substantially differed from the preceding experiments. Subjects completed three successive test blocks and three successive restudy blocks (with the starting order of test or restudy randomly assigned) and with each block

having exactly one trial per concept with no time limit. Thus, subjects completed a total of three test or three restudy trials per concept.

Training methods. Each retrieval-verification-scoring trial involved the following steps (see Figure 3 for an example). First, subjects attempted to answer a difficult fill-in-the-blank question which required retrieval of nearly the entire concept except one essential term. After submitting their answer, the feedback screen appeared. On that screen, the answer attempt was displayed along with the three essential terms for that concept, one of which was the cue in the preceding question. Subjects had to verify whether they had correctly typed each of those terms by marking yes or no. Next, they counted how many terms out of 3 that they had correctly recalled and typed that number as their score. Finally, the whole concept was presented for subjects to copy. By comparison, in the restudy condition, subjects simply viewed and copied whole concepts.

Learning instructions. In the test condition, subjects were encouraged to fully learn each concept and to improve their scores over multiple attempts. In the restudy condition, subjects were told to study.

Materials. The materials consisted of 24 biology concepts in one-sentence form as in the first two experiments. Three difficult fill-in-the-blank test questions were created for each concept. In each, all but one essential term and, in many cases, one article word (i.e., *a*, *an*, or *the*) that preceded that term, was replaced with a continuous blank line or several lines interspersed with punctuation marks. On the criterial test, the terms that were to be retrieved during training were assessed in the tested-same condition and the terms that were cues to training questions were assessed in the tested-different condition. There were 8 tested-same, 4 tested-different, and 12 restudied questions per criterial test block. All other materials were largely identical to those used in prior experiments.

Data coding. Difficult fill-in-the-blank questions were computer scored in terms of the number of essential terms correctly recalled per concept.

Results and Discussion

Initial study and training. Subjects spent an average of 14 min, or 34 s per concept, during initial study. During training, mean subject performance improved across each of three test trials per concept (Table 2), reaching $M = 0.59$ by the third iteration. As expected, the more time-consuming nature of retrieval-verification-scoring trials (subjects spent an average of 84 s each vs. 26 s for restudy) resulted in a large time-on-task difference; subjects spent an average of 47 min to complete three repetitions per tested concept, versus only 15 min for restudy.

Criterial test. Results are listed in Table 3 and depicted in Figure 2, panel e; ANOVA results are detailed in Table 4. As is evident in the figure, there was evidence of positive transfer relative to restudy. Performance was best overall in the tested-same condition, second best in the tested-different condition, and lowest in the restudied condition. Thus, the use of retrieval-verification-scoring trials – a method that directed subjects to attend to the essential terms of each concept, highlighted the importance of correctly recalling and verifying exact terms, and encouraged and provided the opportunity to closely examine entire concepts (albeit with much greater time required under self-paced training conditions) – elevated performance for both tested and untested terms above that of conventional restudy.

Experiment 6

Having demonstrated a method of cued recall with extensively processed feedback that successfully yielded transfer relative to restudy, for the final experiment we attempted to replicate that finding under conditions of strict control for time-on-task, fixed-paced training, and equal training phase item repetitions. We also included a modified restudy control that was potentially more competitive with testing.

Method

Subjects. Forty-eight subjects participated. Data from 5 subjects were excluded due to computer or experimenter errors, and 3 subjects were unable to fully comply with instructions, leaving 40 subjects' data for analysis.

Design, procedure, and materials. This experiment incorporated the design of its predecessor with the following changes: there was a fixed time limit of 70 s for both test and restudy trials (and for retrieval-verification-scoring trials, 30 s for testing and 40 s for feedback), and there were two repetitions of either testing or restudy trials for each concept across contiguous blocks (four training blocks in total). Thus, in this design, subjects that had not fully completed all steps of a retrieval-verification-scoring trial by the trial time limit were not permitted to do so and immediately began the next trial. Time limits were chosen based on prior experiment data and experiment timeslot logistics. Additionally, in the restudy condition, the three essential terms were shown alongside the whole concept for one-third of restudied concepts (with the selection of concepts for which terms were shown counterbalanced across training lists). Subjects were informed that those terms, where present, were additional information for them to study. This was intended to further control for the display of terms during retrieval-verification-scoring. Materials were otherwise identical to that of the prior experiment.

Initial study and training. Subjects spent an average of 14 min, or 36 s per concept, during initial study. Performance improved over the two test trials per tested concept (Table 2), reaching $M = 0.41$ by the second iteration.

Criterial test. Because criterial test performance in the restudied condition for concepts with essential terms displayed was not better than restudied concepts without terms displayed ($M = 0.61$ for both; data averaged across criterial test blocks), suggesting that the presence of those terms during some restudy trials was ineffective at improving performance, data from restudied

concepts that did or did not have terms separately displayed during training were combined in the analyses. Results are listed in Table 3 and depicted in Figure 2, panel f; ANOVA results are detailed in Table 4. We again observed evidence of positive transfer relative to restudy, replicating the results of the preceding experiment. Thus, the results of the Experiments 5 and 6 indicate that cued recall combined with extensive feedback processing – at a level substantially beyond that used in earlier experiments – can yield transfer from tested to untested terms.

General Discussion

In the forgoing experiments we explored whether a series of cued recall-based training and feedback methods could yield transfer for process-based biology concepts. This research encompassed fill-in-the-blank questions, process step questions, order questions, and inference questions, none of which appeared to be sufficient alone to induce transfer. Additionally, enrichment of initial study using diagrams and definitions, extended initial study periods, immediate or delayed feedback, repeated feedback, or feedback which contained whole concepts or process timelines was insufficient to generate transfer. Rather, criterial test performance in the tested-different condition was in all of those cases (Experiments 1 through 4) nearly equivalent or numerically lower than that in the restudied condition, just as occurred in prior work on this topic (excepting paired associate materials; see Carpenter, Pashler, & Vul, 2006; Rickard & Pan, 2018). Those results underscore the nontrivial challenge of designing a task that produces transfer of cued recall learning on a process-based concept to previously untested terms from that concept. Ultimately, the use of substantially more extensive feedback methods (Experiments 5 and 6) which required subjects to check and verify different components of each concept, followed by copying that concept, was necessary to generate transfer.

When Indirect Effects of Testing May Yield Transfer

The absence of transfer in Experiments 2 through 4 is particularly notable given that the

post-retrieval elaborated feedback methods used in those experiments resembled that used in prior studies in which indirect transfer of various types has been observed (e.g., Butler et al., 2013; McDaniel, Anderson et al., 2007; cf. McDaniel, Wildman, & Anderson, 2012). Those contrasting results invite further consideration of the conditions under which various feedback types are effective at yielding transfer.

The efficacy of different feedback types. Regarding the delayed, extended, and in some cases repeated feedback of McDaniel, Anderson, et al. and Experiment 2 of the present work, two general differences between that study and this experiment may account for the contrasting transfer results, although neither possibility can at present be clearly linked to a psychological mechanism. First, the authentic educational context and longer learning interval (i.e., up to three weeks instead of 48 hrs) in that study may have been pivotal. During that time, students likely took advantage of repeated and spaced feedback learning opportunities, plus studied relevant course materials. Post-retrieval study of materials (i.e., reading text passages or chapters) has also been employed in several other retrieval practice studies that observed positive transfer to application and inference questions (e.g., Karpicke & Blunt, 2011; Lechuga, Ortega-Tudela, & Gómez-Ariza, 2015; McDaniel, Bugg, Liu, & Brick, 2015; McDaniel, Howard, & Einstein, 2009). Moreover, the online quizzing and feedback platform used in McDaniel, Anderson, et al. has since been used to successfully generate transfer between factual and application questions (Thomas, Weywadt, Anderson, Martinez-Papponi, & McDaniel, 2017; cf. McDaniel, Wildman, et al., 2012, described further next). Second, transfer may be easier to achieve for the neuroscience facts used in that study than for the process-based concepts of the present work.

Further, transfer of different types (i.e., to application and inference questions and to untested materials seen during the initial study phase, respectively) than that pursued in the present experiments was the focus of Butler et al. (2013) and McDaniel, Wildman, et al. (2012),

both of which used explanatory feedback (which was comparable to the whole concept feedback and process timelines used in Experiments 2 through 4). A recent meta-analytic review found that the effects of retrieval practice on transfer can vary substantially by transfer type and tend to be more robust for application and inference questions than to untested materials seen during initial study or across terms from a fact or other multi-element stimulus (Pan & Rickard, 2018). Additionally, explanatory feedback has not always yielded strong positive transfer relative to restudy in prior work (e.g., it was observed in Butler et al. but was not significant in McDaniel, Wildman, et al., although there were differences in the amount of explanatory content provided). Given the current results, it follows that indirect transfer is not an assured consequence of even deliberately implemented post-retrieval elaboration in the form of either explanatory feedback or many of the other aforementioned feedback types.

Retrieval-verification-scoring and transfer. When we did observe transfer, it required extensive post-retrieval study-like activities. For Experiment 5, we interpreted the observed transfer as reflecting indirect effects of retrieval practice, although that inference was tentative due to a potential time-on-task confound. That confound was eliminated in Experiment 6, and more complete (albeit smaller in magnitude) transfer was observed. Thus, we conclude based on those experiments that it is possible to achieve indirect transfer of test-based learning for process-based concepts, but that such transfer may require any or all of the post-retrieval activities used in the retrieval-verification-scoring procedure.

Retrieval-verification-scoring differed from the feedback presentation and processing methods used in prior experiments in four major ways. First, the verification step directed subjects' attention to each of the essential terms per concept, including the term that was later assessed in the tested-different condition on the criterial test. Second, that step provided subjects with firsthand knowledge of the importance of fully and exactly recalling key components of

each concept. Third, the scoring step furnished subjects with a numerical measure of their mastery of each concept. This may have corrected inaccurate judgments of learning and motivated greater learning on subsequent trials. Finally, all of these feedback processing steps may have enhanced the efficacy of the final copying step. Overall, a prerequisite for transfer from tested to untested terms appears to be training procedures that deliberately focus learners' attention to those terms during feedback and not just instructional prompts, the provision of more explanatory details, or other types of elaborative information.

Limitations, Educational Implications, and Future Work

The reader might suspect that the lack of transfer in Experiments 1 through 4 reflects the fact that subjects did not undergo deep conceptual learning during either the initial study or training phases. We are open to that possibility, even in the case of extensive initial study in Experiment 2. If true, however, it does not necessarily constitute a weakness of this work from the applied perspective. We are probably not alone in our strong intuition that the onset of deep conceptual understanding in STEM fields lags the acquisition of facts and of more tenuous, and often piecewise, conceptual understanding. Further, progress through those levels may be necessary for achieving deeper understanding (Anderson & Krathwohl, 2001). In that light, the current insights regarding transfer may be especially applicable to classroom-based cued recall tests with feedback, particularly for novice and intermediate students. It is also important to recognize that the new manipulations that improved transfer in Experiments 5 and 6 (i.e., retrieval-verification-scoring) are unlikely to have yielded a substantial leap in deep understanding relative to Experiments 2 through 4. Rather, that transfer likely reflects the greater efficacy relative to restudy of those manipulations in focusing subjects' attention on the entire stimulus presented on practice test trials compared to restudy. Future work that further explores the critical properties of activities that produce indirect transfer, and especially feedback

methods such as the retrieval-verification-scoring method employed here, is warranted.

Our demonstration of retrieval-verification-scoring also represents a proof-of-concept for more complex (but potentially more effective, contingent on learning objective) forms of cued recall practice that may not only be useful for improving transfer across terms for process-based concepts and other stimuli (e.g., multi-term facts), but also for computer-based training programs more generally. Such methods could be refined (i.e., made more efficient) via the use of automated scoring procedures, adaptive algorithms that tailor training schedules to performance levels, or even gamification that incorporates the goal of score improvement over training trials. As retrieval practice research increasingly addresses issues of practical application, more sophisticated implementations of retrieval practice may emerge as a highly competitive alternative to conventional cued recall methods.

Footnote

1. Whole concept feedback arguably could be described as *explanatory feedback* given that it includes an explanation of the entire process-based concept.
2. In McDaniel, Anderson et al. (2007), cued recall and multiple-choice quiz formats were used across different weeks, with assignment of materials to each quiz counterbalanced. We focused on the cued recall results here as they are most relevant.

Note. *, **, and *** indicate significant at $p < .05$, $< .01$, and $< .0001$, respectively.

Figure Legend

- Figure 1. Example initial study and cued recall training test trials (top and bottom panels, respectively). During initial study, concepts are shown with diagrams and definitions. During the training phase, concepts are trained using cued recall (fill-in-the-blank example from Experiments 1-2 displayed) or restudied (not shown).
- Figure 2. Criterial test results of Experiments 1-6. Error bars are standard errors based on the interaction error term of a within-subjects analysis of variance on subject-level mean accuracy scores (based on Loftus & Masson, 1994).
- Figure 3. Example *retrieval-verification-scoring* trial. First panel: difficult fill-in-the-blank question. Second panel: subjects check their answer for essential terms. Third panel: numerical scoring. Fourth panel: whole concept presented for word-for-word copying.

Study this concept, then press ENTER.

In the process of gastrulation, gastrulas are formed when an embryo organizes into three germ layers.

DEFINITIONS:

Gastrula: an embryo that is organized in three germ layers.

Embryo: the earliest stage of development for multicellular organisms.

Germ: a layer that is a group of cells in an embryo.

embryo → gastrula
germ layers

Type the missing word.

Gastrulas are formed when an _____ reorganizes into three germ layers?

Figure 1. Example initial study and cued recall training test trials (top and bottom panels, respectively). During initial study, concepts are shown with diagrams and definitions. During the training phase, concepts are trained using cued recall (fill-in-the-blank example from Experiments 1-2 displayed) or restudied (not shown).

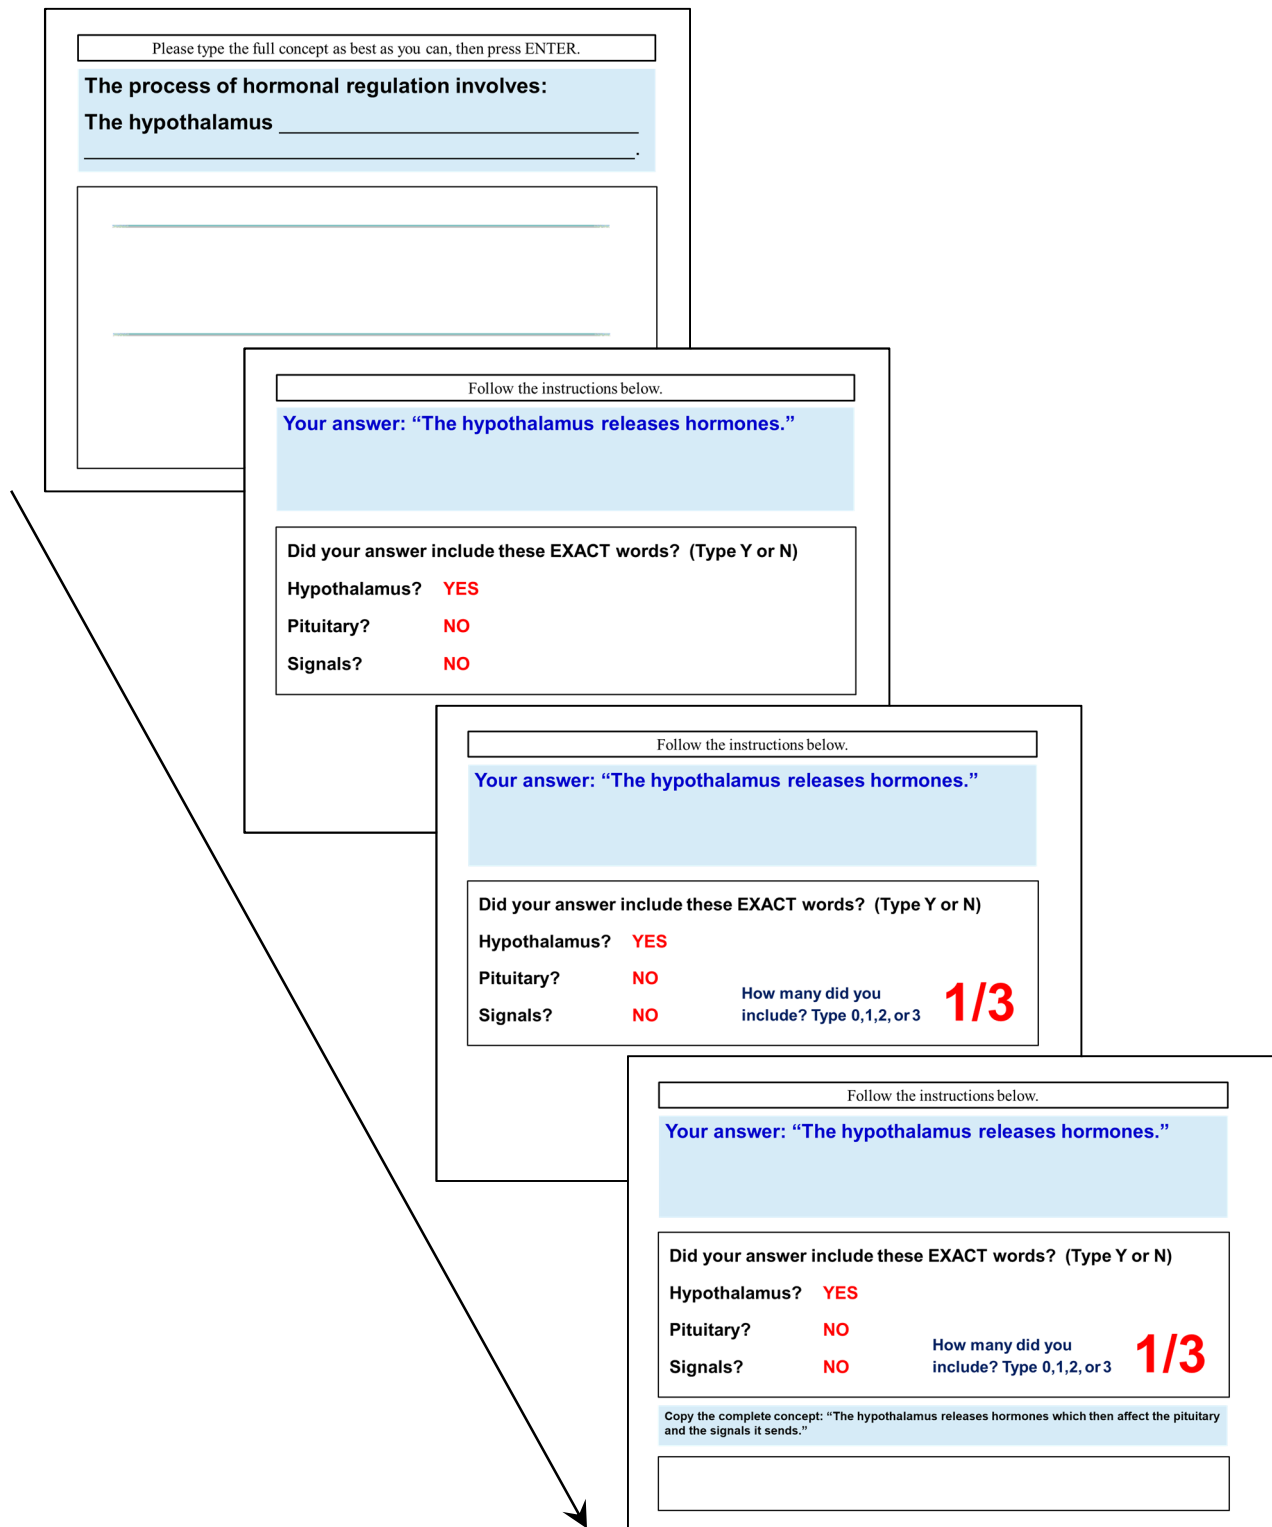

Figure 3. Example retrieval-verification-scoring trial used in Experiments 5-6. First panel: difficult fill-in-the-blank question. Second panel: subjects check their answer for essential terms. Third panel: numerical scoring. Fourth panel: whole concept presented for word-for-word copying.

Appendix A

List of Process-Based Biology Concepts

Concept no.	Concept name	Example essential terms
1	Active transport	antiporter, hydrogen, sodium
2	Audioception	cochlea, hair, pinna
3	Baleen filtration	filter, plankton, whale
4	Blood flow	capillaries, oxygen, vein
5	Endosymbiotic theory	endosymbiosis, mitochondria, protist
6	Enzyme catalysis	enzyme, product, substrate
7	Exocytosis	plasma, vesicle, waste
8	Gastrulation	embryo, gastrula, germ
9	Hormonal signaling	hypothalamus, pituitary, signals
10	Immune response	clone, infection, lymphocyte
11	Membrane formation	bilayer, phospholipid, tails
12	Movement initiation	CNS, effector, receptor
13	Muscle contraction	actin, discs, myosin
14	Neuronal signaling	axon, dendrite, soma
15	Ophthalmoception	bipolar, ganglion, light
16	Paracrine signaling	cell, paracrine, target
17	Passive transport	concentration, diffuse, equilibrium
18	Photosynthesis	chloroplast, light, thylakoid
19	Phylogenetic representation	ancestor, branch, node
20	Protein synthesis	RNA, transcription, translation
21	Reflex arc	interneuron, motor, sensory
22	Sexual reproduction	gametes, meiosis, organism
23	Upwelling	coastline, current, wind
24	Viral reproduction	generation, host, virus
25	Allopatric speciation	evolution, isolation, species
26	Cellular respiration	ATP, phosphate, sugar
27	Condensation reaction	condensation, covalent, hydroxyl
28	Crossing over	chiasma, chromatid, genetic
29	Dehydration reaction	bond, dehydration, monomer
30	Gene flow	allele, flow, population
31	Hydrolysis	hydrolysis, polymer, water
32	Lipid digestion	bile, fat, lipase
33	Membrane potential	electrochemical, ion, membrane
34	Metabolism	bacteria, carbohydrate, pyruvate
35	Mitosis	centromere, chromosome, mitosis
36	Plasmogamy	fertilization, fungi, plasmogamy

Note. For Experiments 1, 3, and 4, concept numbers 25-36 were also used. As described in the text, some concept names and terms were modified (i.e., replaced with synonyms) where necessary for certain question types. No. = number.

Appendix B

Training Phase Question Subtypes and Feedback Examples

Exp.	Question subtype	Example	Feedback
Term retrieval			
1	Fill-in-the-blank	<i>The hypothalamus releases hormones which then affect the _____ and the signals it sends.</i>	<i>pituitary</i>
2	Fill-in-the-blank	<i>The hypothalamus releases hormones which then affect the _____ and the signals it sends.</i>	<i>Correct answer: pituitary The hypothalamus releases hormones; those hormones affect the pituitary and the signals that it sends. Process: hypothalamus – hormones – pituitary – signals</i>
Higher order questions			
3, 4	Process step	<i>Hormonal signaling involves two main steps. What occurs in the first step? Answer completely with all details.</i>	<i>First, the hypothalamus releases hormones. Second, those hormones affect the pituitary and the signals it sends.</i>
3	Order	<i>In hormonal signaling, what is involved first? The hypothalamus or the pituitary?</i>	<i>First, the hypothalamus releases hormones. Second, those hormones affect the pituitary and the signals it sends.</i>
4	Inference	<i>What serves as the ultimate “control center” that is in charge of the entire process?</i>	<i>First, the hypothalamus releases hormones. Second, those hormones affect the pituitary and the signals it sends.</i>
Retrieval-verification-scoring			
5, 6	Difficult fill-in-the-blank	<i>The process of hormonal regulation involves: The hypothalamus _____ _____.</i>	<i>Did your answer include these exact words (yes or no)? Hypothalamus? Pituitary? Signals? How many out of those three did you include? Concept: the hypothalamus releases hormones which then affect the pituitary and the signals it sends.</i>

Note: Exp. = Experiment.

Appendix C

Example Concept Paragraph Used During Initial Study in Experiment 2

Protein synthesis is the process by which a cell makes protein. It involves DNA, a molecule that contains genetic information, and RNA, a modified version of DNA. The process is as follows: first, DNA is copied to RNA via transcription. Second, RNA is coded into protein via translation. The process therefore involves two steps: transcription and then translation. The order of the components is: DNA to RNA to protein.
